

A logotype is drawn, not typed

You're right that setting the name in the heading font isn't a mark. A wordmark earns its keep when one letter does a job no font gives you for free.

For Nori there's an obvious candidate: the dot on the *i*. Make that the seed and the symbol and the name stop being two things — the logo works with or without the sheet, and the name becomes unmistakable in a feed of grey app icons.

STUDY A

As it stands

Caprasimo, typed, default spacing, capital N. Perfectly usable and completely unowned — anyone with the font has it.

Nori

Baseline for comparison.

STUDY B — RECOMMENDED

The seed is the tittle

All lowercase, tightened a touch, and the dot on the *i* redrawn as the sage seed — larger than a normal tittle and sitting slightly right, so it reads as a seed resting on the letter. The sheet becomes optional: the word alone is now the mark.

nori

nori

nori

nori

Holds to 17px. Below that the seed goes ink and behaves as a normal dot.

ni

ni

The icon crops to *n* and the seeded *i* — recognisable at 18px without the full word.

STUDY C

Sheet in the counter of the o

The seed drops into the bowl of the *o* instead — a plate seen from above. Charming and a little more literal; it competes with the tittle, so it can't run alongside Study B.

nori

Needs the counter to stay open — fails below about 32px, so it stays a large-format variant.

STUDY D

Formal, letterspaced caps

For contracts, clinical materials and the footer of an exported report: Figtree caps, wide tracking, no seed. A quiet companion to the main mark rather than a replacement.

N O R I

Pairs with the sheet mark when the setting needs to feel institutional.

MY RECOMMENDATION

Study B, with the sheet kept only for the app icon and favicon.

One idea does two jobs: the seed that means "the thing you couldn't see" lives inside the name itself. Lowercase suits a product you talk to, it survives to 17px, and the cropped *ni* gives you a symbol without inventing a second shape.

WHAT PROPER DRAWING ADDS

These are set in the live font, so spacing is approximate. A real logotype gets the *n–o* join kerned by eye, the *o* trued to a circle, the seed aligned to the stem, and then it's outlined as vectors so it never depends on the font loading.

NEXT

Tell me which study to take forward and I'll roll it through the guidelines, landing page and app screens, with the seed logic applied consistently across sizes.
